When assessing patients for fertility investigation or egg freezing, it is important to take into consideration the female's age as this impacts the chance of natural conception and impacts the risk of aneuploidy and miscarriage. The graphs below provide a reference for this information.

Monthly chance of natural conception

Maternal age and prevalence of aneuploidy

Guidelines for initial infertility investigations

Initial infertility investigations should start if the female patient is under 35 and trying to conceive for 12 months OR over 35 has been trying to conceive for 6 months. To expedite the referral process, we request that these investigations are initiated prior to referral to one of our Fertility Specialists.

Female investigations

- Preconception screen:**
- BMI (incl. height + weight)
 - blood group and antibodies
 - FBC + iron studies (and thalassaemia screen as indicated)
 - Rubella, varicella, syphilis, hepatitis B and C and HIV serology
 - TSH (aim for < 2.5)
 - Vitamin D, prolactin, free androgen index (FAI)
 - Karyotype
- Fertility hormones:**
- FSH, LH, oestradiol (all day 2-6), AMH
 - Luteal progesterone
- Ultrasound:**
- Pelvic ultrasound and request antral follicle count

Male investigations

- Preconception screen:**
- Hepatitis B/C and HIV serology
 - Syphilis
- Fertility hormones:**
- LH, FSH, testosterone, SHBG
- Karyotype**
- Semen analysis:**
- | Element | Reference |
|----------------------|-----------------|
| Volume | ≥ 1.5mL |
| Concentration | ≥ 15 million/mL |
| Progressive mobility | ≥ 32% |
| Normal morphology | ≥ 4% |
| Antisperm antibodies | > 50% |
